**H-TDMA**

**Gas-solid/liquid reaction, kinetics**

**cavity ring down spectrometry: aerosol extinction**

# Gas-solid kinetics: Mechanism

$$r = \frac{d\{\text{SO}_4^{2-}\}}{dt} = \frac{k_1 k_2}{k_{-1} + k_2} [\text{SO}_2] = k[\text{SO}_2]$$

$$k = \frac{k_1 k_2}{k_{-1} + k_2}$$

Limiting cases :  $k = \frac{k_1 k_2}{k_{-1} + k_2}$

(1) 当  $k_{-1} \ll k_2$  时,  $k = k_1$ ; **250-230K**

$$E_a = RT^2 \frac{d \ln k}{d(1/T)} = RT^2 \frac{d \ln k_1}{d(1/T)} = E_{a1}$$

The apparent activation energy :  $14.63 \pm 0.20$  kJ/mol

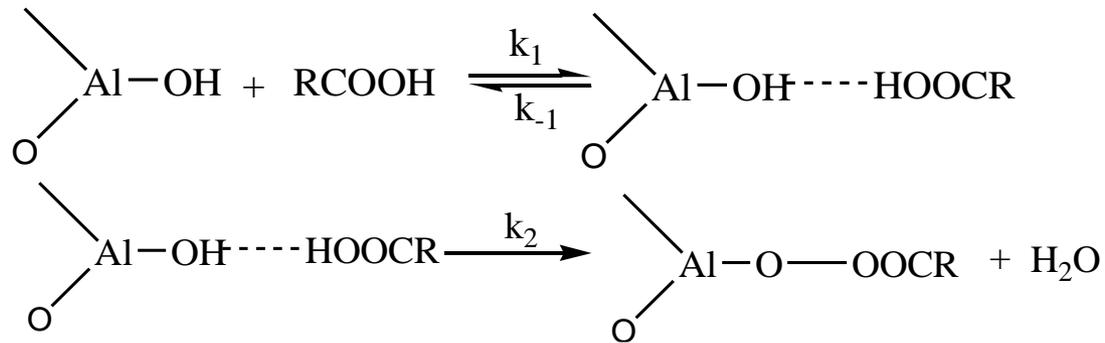

(2) 当  $k_2 \ll k_{-1}$  时,  $\frac{k_1 k_2}{k_{-1}} = K k_2$  ; **298-250K**

$$E_a = RT^2 \frac{d \ln k}{d(1/T)} = RT^2 \frac{d \ln (K k_2)}{d(1/T)} = RT^2 \frac{d \ln (K)}{d(1/T)} + RT^2 \frac{d \ln (k_2)}{d(1/T)} = \Delta H_{ads} + E_{a2}$$

**The balance between the two limiting cases can be used to interpret the turning point on the rate of sulfate formation.**

# Gas-solid kinetics: Mechanism

## Organic acid on mineral dust

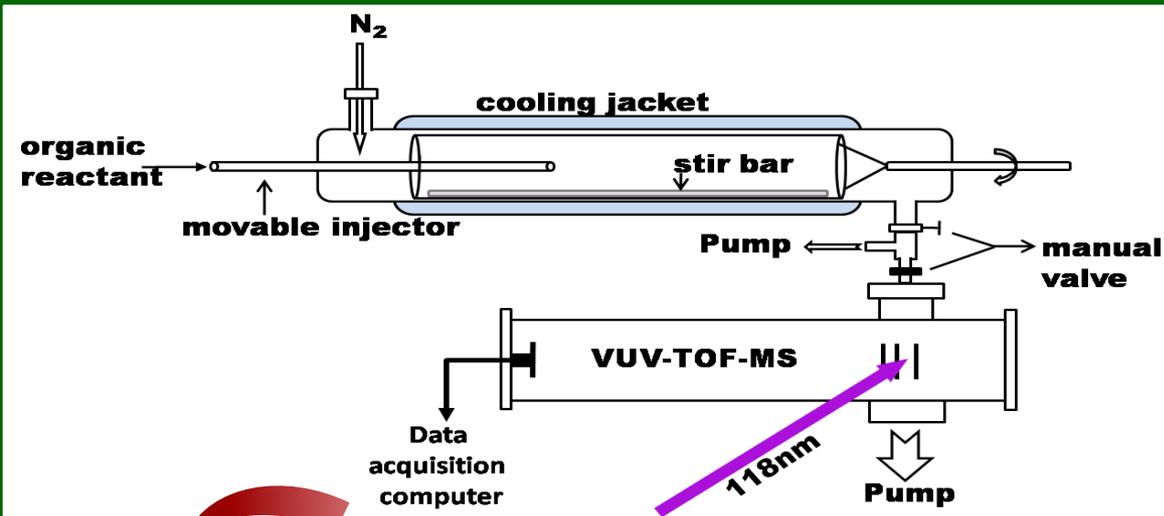

Heterogeneous process: Important

### Atmospheric lifetime

	dust	OH
HCOOH	8-13h	86 days
CH <sub>3</sub> COOH	4-5h	46days

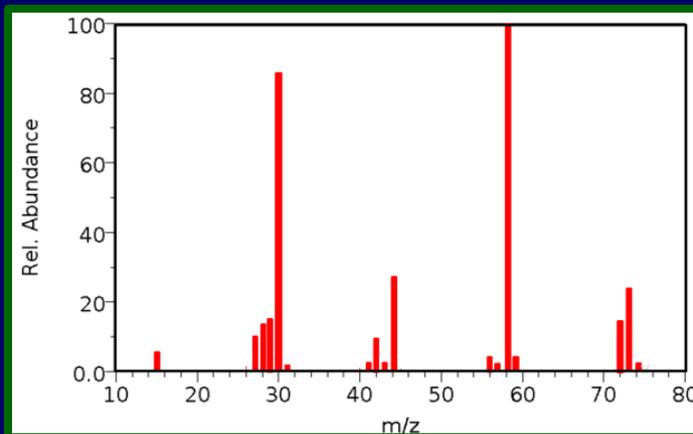

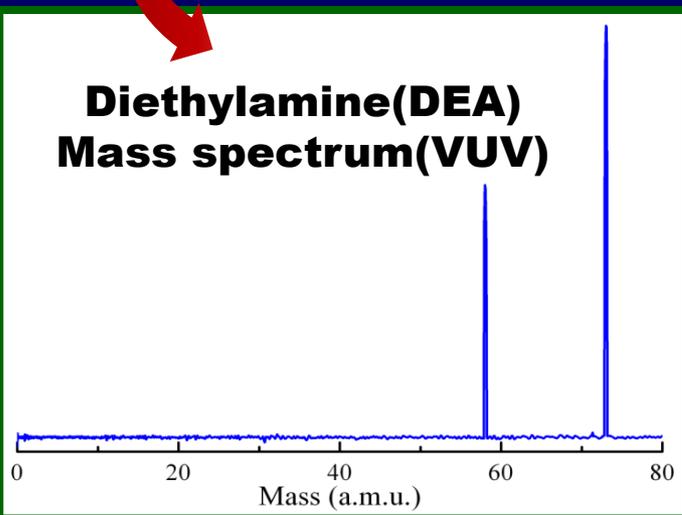

$$\tau = \frac{4}{\gamma \langle v \rangle SA} \quad SA = 150 \mu\text{m}^2 \text{ cm}^{-3}$$

# Gas-liquid Kinetics

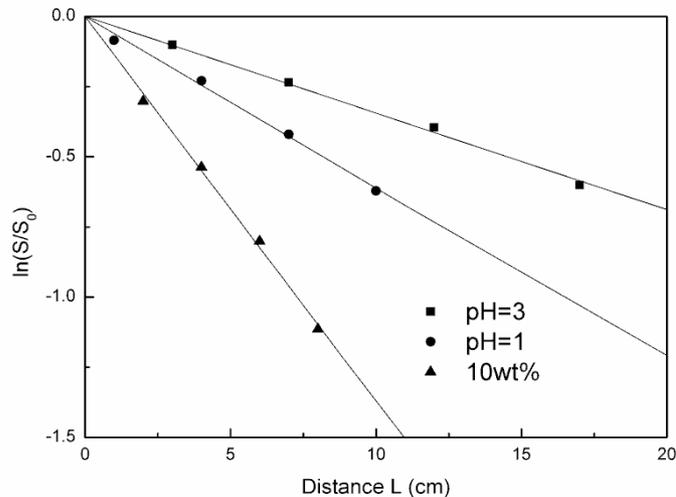

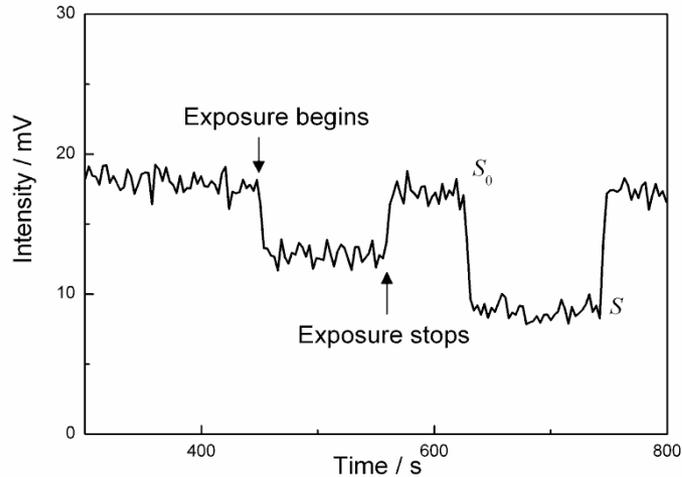

**Schematic diagram of experimental setup  
Rotating Wetted-Wall Flow Tube PIMS**

**Diethylamine(DEA)  
Mass spectrum(VUV)**

**NIST:DEA MS (EI)**

# Gas-liquid Kinetics

**First-order rate  $k_{obs}$ :**

$$\ln(S / S_0) = -k_{obs} L / v_{ave}$$

**Diffusion-limited rate  $k_{diff}$ :**

$$k_{diff} = 3.66 D_i / r^2$$

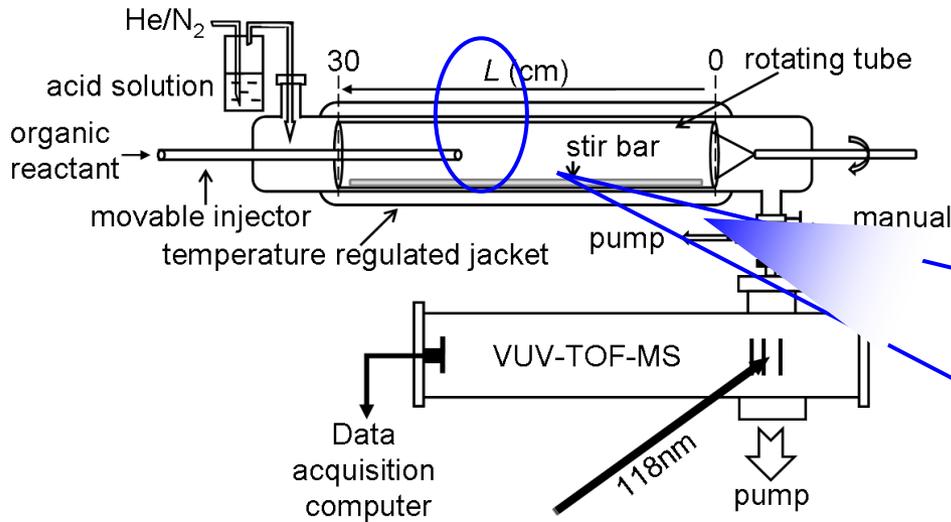

**Surface rate constant  $k$ :**

$$1 / k = 1 / k_{obs} - 1 / k_{diff}$$

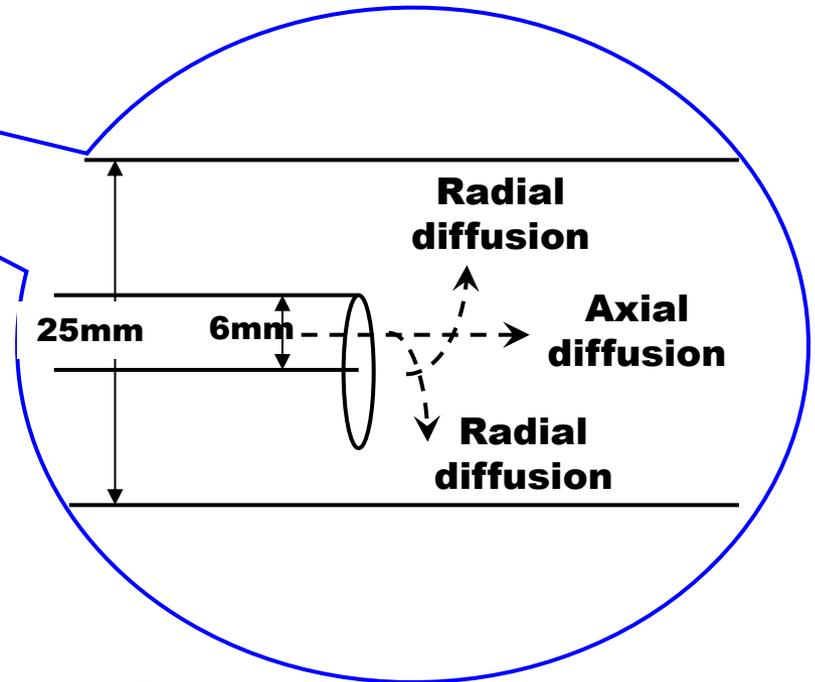

**Reactive uptake coefficient:**

$$\gamma = \frac{4kV}{wA}$$

# Gas-liquid Kinetics

**Restrain diffusion  
Is possible!**

## ➤ Axial diffusion

If The system Peclet Number **sufficiently large** the axial **diffusion** velocity will be much less than the **flow** velocity

$$Pe = 2rv/D_i; \quad Pe \geq 10 \text{ is necessary,}$$

$$k_{diff} = K_d \cdot D_i / r^2 \quad (K_d = 3.66)$$

## ➤ Radial diffusion

The precondition:  $k_{obs} < k_{diff} / 2$

$$0.5 < k_{obs} / k < 1$$

**Carefully design !**

# Epoxide

- The uptake of two epoxides under different pressures :

	H <sub>2</sub> SO <sub>4</sub>	P(Torr)	$\gamma \pm 1\sigma (\times 10^{-5})$
isoprene epoxide	pH=3	180.0	$1.89 \pm 0.14$
		46.0	$1.87 \pm 0.09$
butadiene diepoxide	pH=7	131.0	$8.78 \pm 0.21$
		65.5	$8.49 \pm 0.15$

- Using rotating cylinder with inner radius of 8 mm for isoprene epoxide

		$r = 12.5 \text{ mm}$		$r = 8.0 \text{ mm}$		
H <sub>2</sub> SO <sub>4</sub>	P (Torr)	$k_{diff}$	$\gamma \pm 1\sigma (\times 10^{-4})$	P (Torr)	$k_{diff}$	$\gamma \pm 1\sigma (\times 10^{-4})$
pH=3	180.0	0.976	$0.189 \pm 0.014$	46.0	18.354	$0.189 \pm 0.006$
1 wt %	48.2	3.510	$2.78 \pm 0.083$	26.2	26.734	$2.81 \pm 0.057$
10 wt %	27.1	10.336	$7.99 \pm 0.116$	25.2	28.901	$8.14 \pm 0.180$

# Role of $\text{H}_2\text{O}_2$ : $\text{MBO} + \text{H}_2\text{SO}_4$

**MBO: 2-methyl-3-buten-2-ol**

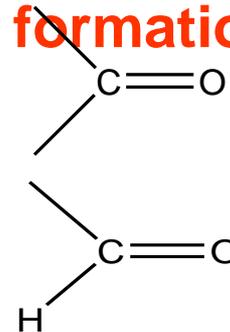

- ◆  $\text{H}_2\text{SO}_4$   
OH disappear  
C=C increase

# ICCAS-TRC (twin-reactor chamber)

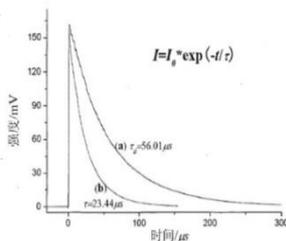

Smog chamber with various instruments for gas and particle measurements

# Cavity ring down spectroscopy

CRDS consists of **two highly reflective concave mirrors** with a reflectivity of 99.995%

**The extinction coefficient is computed** by comparing the **decay time ( $\tau$ )** of a pulse laser trapped in the resonator both with and without aerosol

$$\alpha_{\text{ext}} = \frac{L}{cd} \left( \frac{1}{\tau_0} - \frac{1}{\tau} \right)$$

$$\alpha_{\text{ext}} = N\sigma_{\text{ext}} = \frac{1}{4} \pi D^2 N Q_{\text{ext}}$$

## Advantages

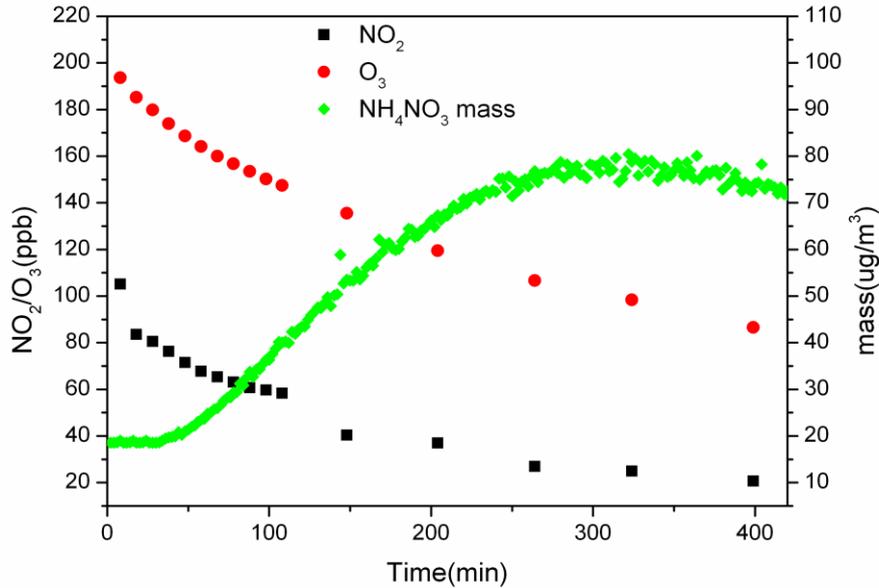

**@immune to shot-to-shot : variations of the laser intensity**

**@measuring the absolute extinction of aerosol sample ; without instrument calibration**

**@high sensitivity**

**@long effective path length**

# Ammonium nitrate formation

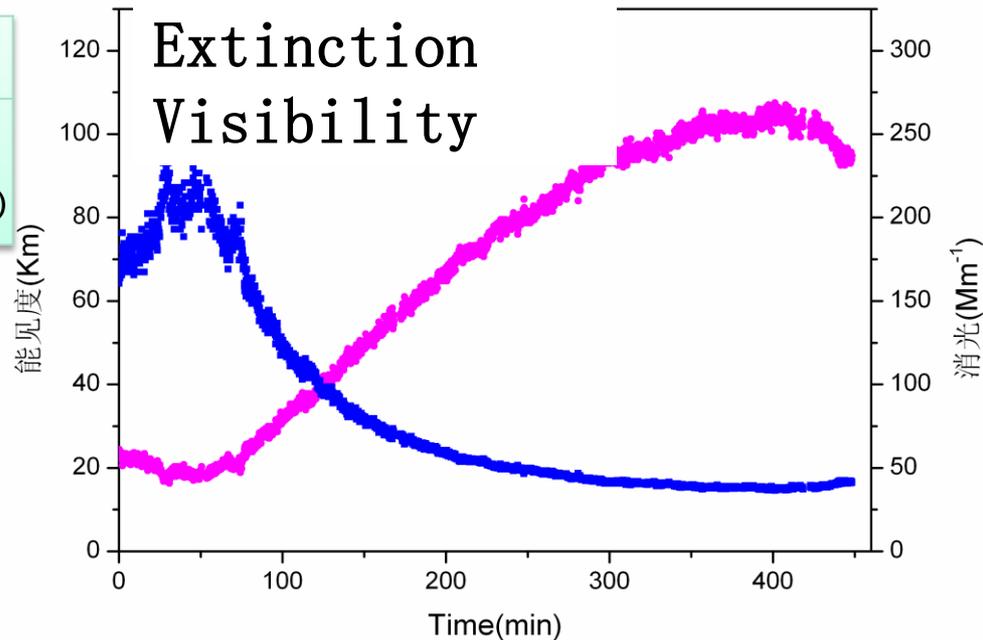

Smog chamber:  
 RH < 30%, rich NH<sub>3</sub>  
 NO<sub>2</sub>, O<sub>3</sub> and seed aerosol  
 NH<sub>4</sub>NO<sub>3</sub> increase  
 continue 7 hour

	NO <sub>3</sub> <sup>-</sup>	NH <sub>4</sub> <sup>+</sup>
velocity (μg.m <sup>-3</sup> .h <sup>-1</sup> )	7.75 (6 obs.)	2.25 (4.5 obs.)

**ICCAS-TRC :**  
**SIA formation experiment**

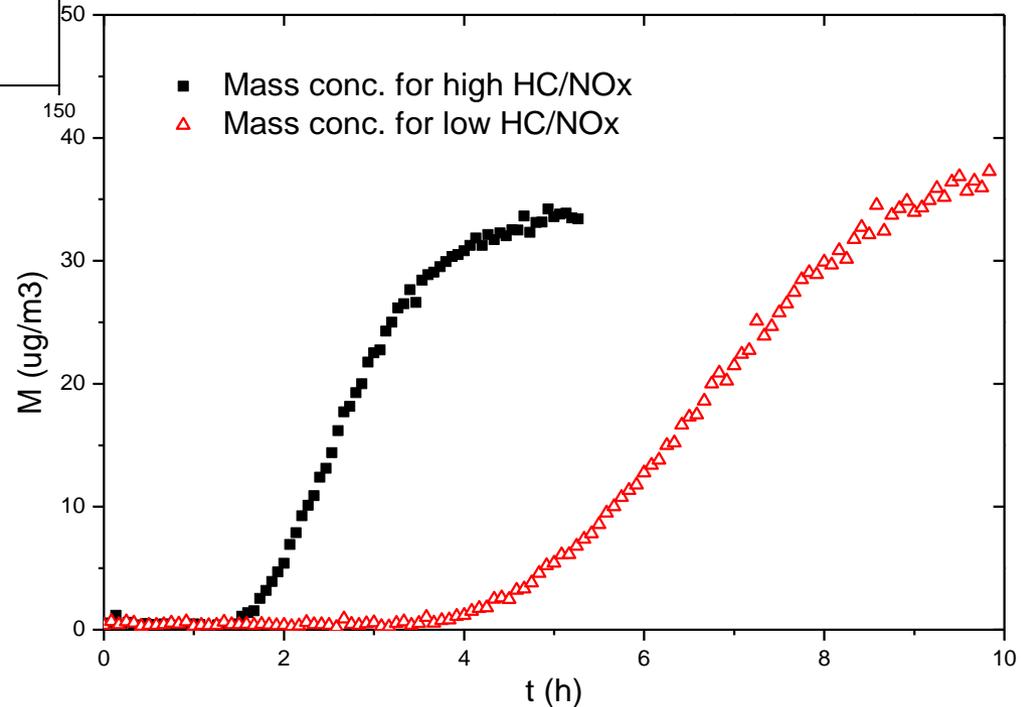

# ICCAS-TRC : SOA formation

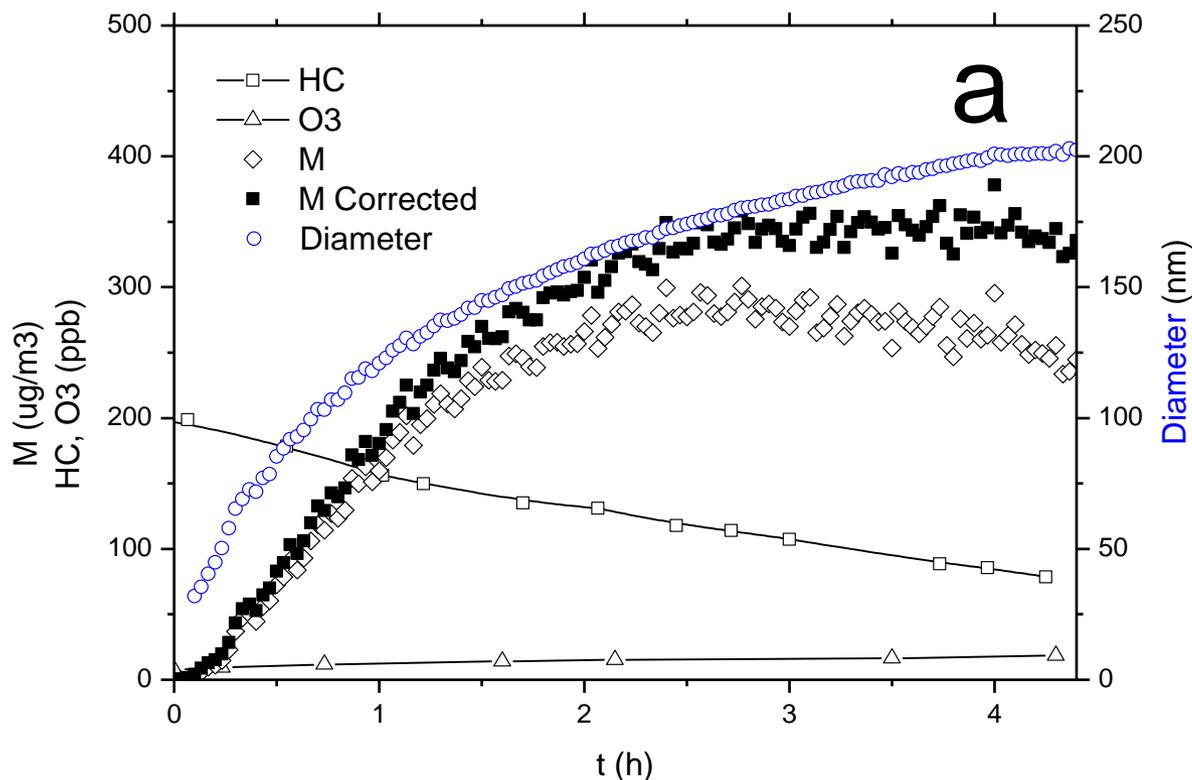

**simulation:**

**Temp, RH, light source, VOCs  
Low & High HC/NO<sub>x</sub>**

**Advantage:  
Measure 2 chamber at the  
same time;  
Change : only single factor,**

# Photooxidation of aromatic hydrocarbons

Finding:  
NO<sub>x</sub> influence  
SOA formation

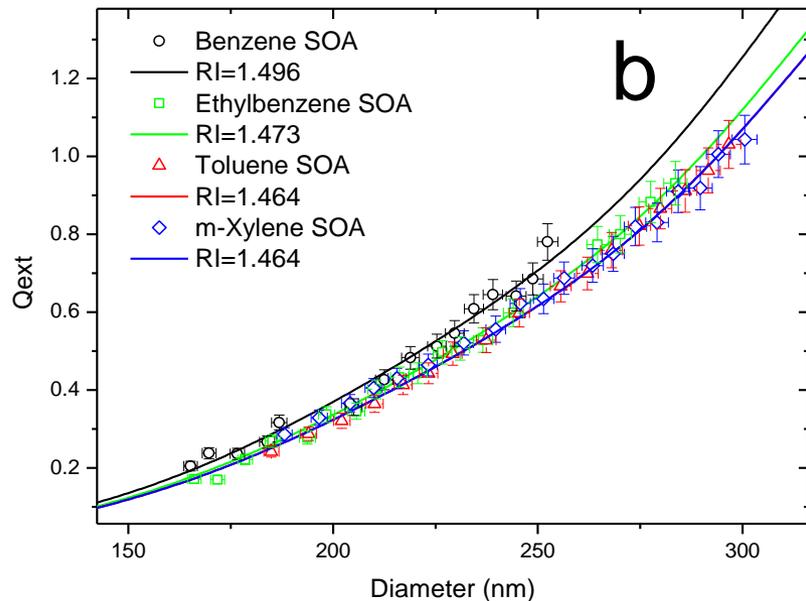

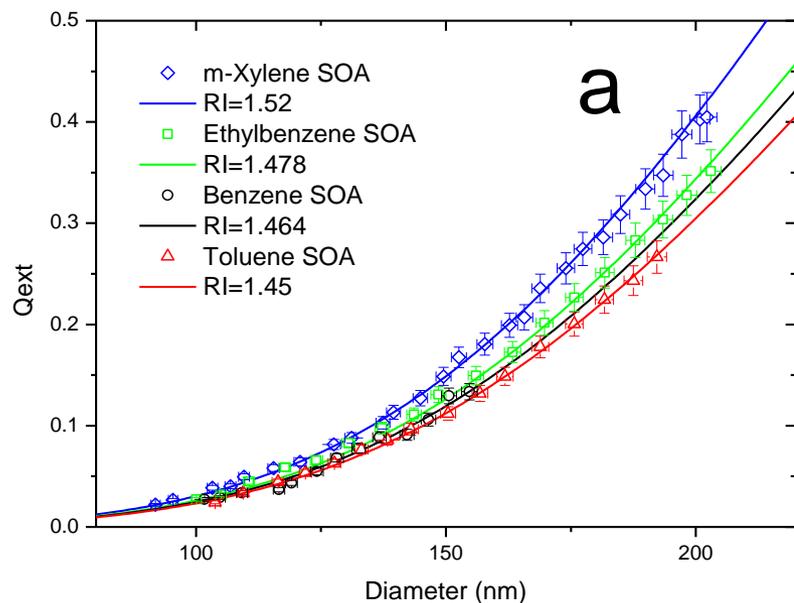

Low NO<sub>x</sub>: PM  
formation just after  
light on  
High NO<sub>x</sub>: PM  
formation need 2 h

**Fig a; low-NO<sub>x</sub> experiment : 200 ppb m-xylene, 5 ppm H<sub>2</sub>O<sub>2</sub>**

**Low-NO<sub>x</sub> experiments:** H<sub>2</sub>O<sub>2</sub> was used as the OH precursor. The background NO<sub>x</sub> level in the chamber : <1 ppb, the initial concentration of H<sub>2</sub>O<sub>2</sub> : 1–5 ppm.

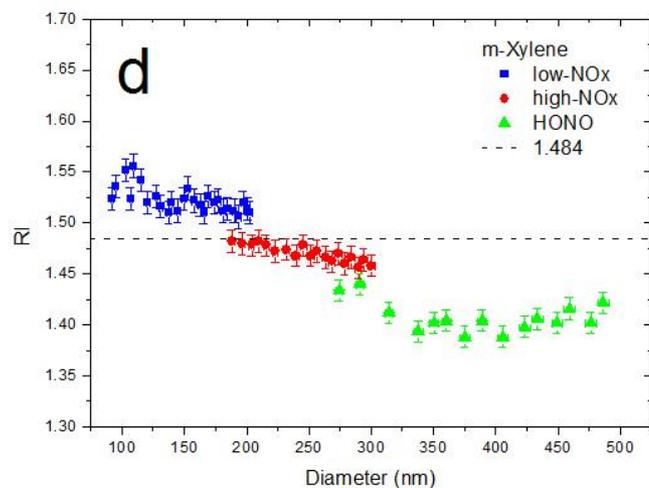

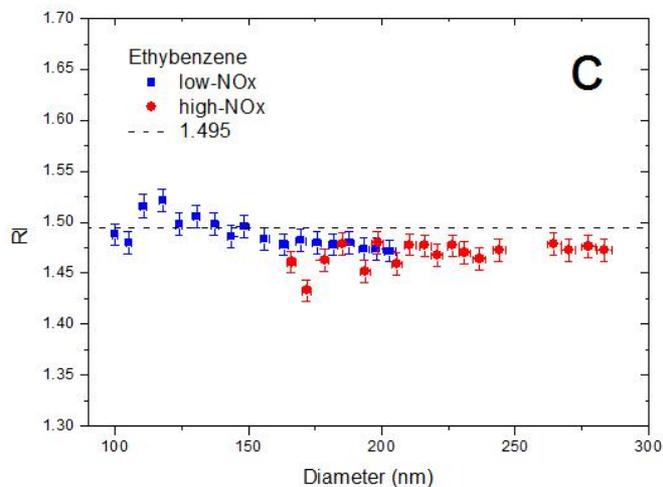

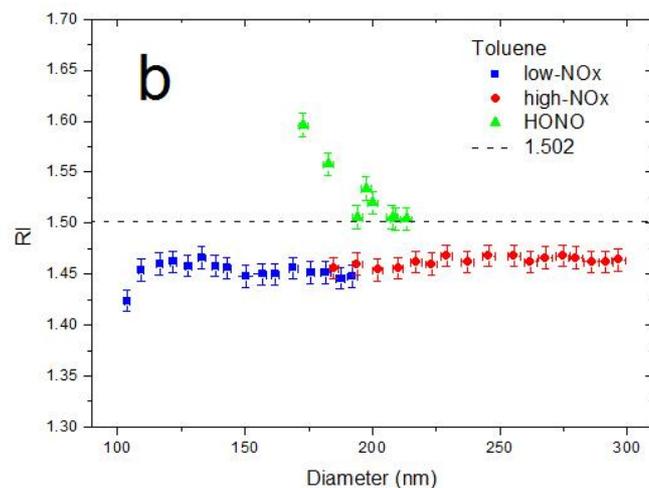

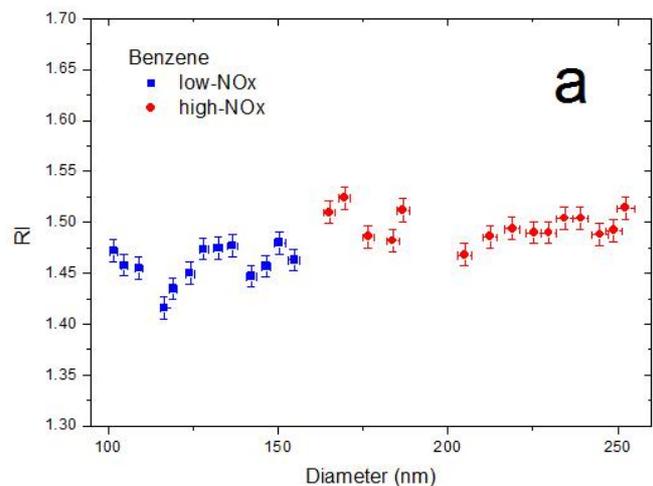

**High-NO<sub>x</sub> :** NO<sub>2</sub> was introduced from a 50 ppm standard gas cylinder.

# Photo-oxidation of aromatic hydrocarbons

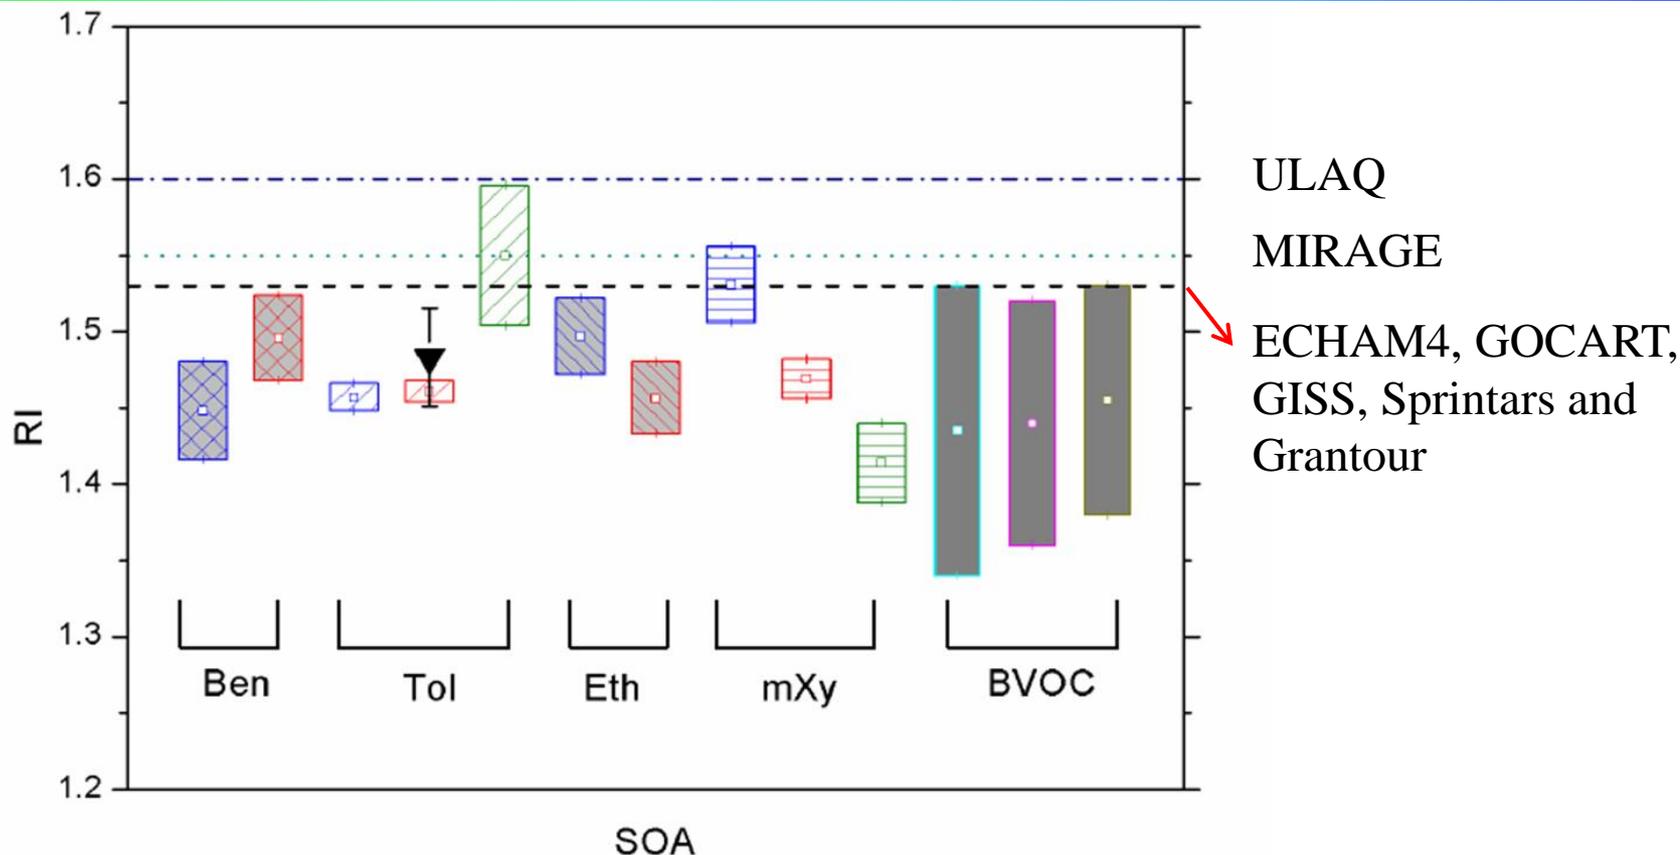

**Dependence of the extinction efficiencies of the SOA particles on the surface mean diameter at a wavelength of 532 nm and the retrieved RIs**  
**(a) low- $NO_x$**   
**(b) high- $NO_x$  experiments**

# Photo-oxidation of aromatic hydrocarbons

The RIs of the SOAs are altered differently as the NO<sub>x</sub> concentration increases as follows: the RIs of the SOAs derived from **benzene and toluene increase**, whereas those of the SOAs derived from **ethylbenzene and m-xylene decrease**.

# Photo-oxidation of aromatic hydrocarbons

**RI** of the different SOA particles: comparison between experimental data & model values. **The commonly used model values for the RIs of organic aerosols are generally higher than the experimental data for the SOAs formed from VOCs, which may cause the overestimation of direct radiative forcing of organic particles to a certain extent.**

# Photo-oxidation of aromatic hydrocarbons

**1, The RIs of the BTEX SOAs are closely related to the initial NO<sub>x</sub> concentration, with different aromatics displaying different trends.**

**For the benzene and toluene SOAs, the RI value increases as the NO<sub>x</sub> level rises, whereas for the ethylbenzene and m-xylene SOAs, the RI value decreases correspondingly. This result is caused by the different molecular structures and the RO<sub>2</sub> + NO pathway that occurs under the high-NO<sub>x</sub> condition.**

**2, The dependence of the RI value on the initial hydrocarbon and oxidant concentrations was also investigated, revealing that the initial concentrations of these reagents have little influence on the optical properties of the SOA.**

**3, For gas-phase oxidation with no seed particles, the BTEX SOAs have no obvious absorption at 532 nm. However, the SOA particles formed under other conditions may absorb light in the visible range, further studies should be performed.**

# **Future Activities**

---

**1 Smog chamber experiments  
SOA formation and extinction properties**
